三個 model 以相同的 weight 合取 ensemble 後, validation accuracy=0.7950, Kaggle private score=0.67038。

2. (1%) 承上題,請用與上述 CNN 接近的參數量,實做簡單的 DNN model,其模型 架構、訓練過程和準確率為何? 試與上題結果做比較,並說明你觀察到了什麼?

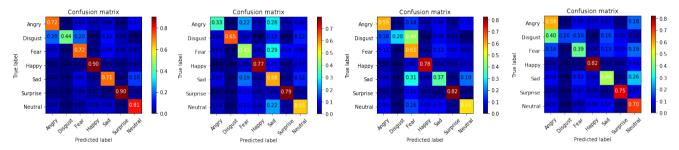

我修改了model_6,作成了約有2900萬個參數的DNN model:

模型架構: [input=2304]→880→1760→2640→3520→2560→960→7

訓練過程: 同 model_6, 100 epochs, batch size=144

準確率: training=0.3959 validation=0.3404 Kaggle private=0.32738 此 DNN 的 Confusion Matrix 顯示,Surprise 認出 0.76,Happy 認出 0.53,其餘的 class 都認不出來,連 training data 都無法 fitting。上題中,training data 至少都有 0.9 以上,顯見卷積層的有無對圖像辨識的成敗有多重要。

3. (1%) 觀察答錯的圖片中,哪些 class 彼此間容易用混? 並說明你觀察到了什麼?

最左為 ensembled model, 其餘依序為三個 model 各自的 Confusion Matrix。

Disgust 的 class 最容易與其他 class 混淆,各有 0.2 的 Disgust 被分成了 An gry 和 Fear。另外 Fear 被認成 Sad、Sad 或 Angry 被認成 Neutral 的情形也很顯著,反倒是 Happy 和 Surprise 不太會被認錯。

按照一般社會常識來推論,正面情緒的表情會有很顯著的特徵,而負面的情緒(如 Angry、Fear、Sad 等)可能都同樣表現出一個「激動」的表情,自然會互相混淆,只能到 0.7 的 Accuracy。

training set 中的 Disgust class 佔比實在太小了,層數高的 model_5 與 mo del_6 都幾乎完全認不出來,因此我將層數雖少卻能將 Disgust 認到 0.6 的 model_3 加入 ensemble,平衡了另兩個 model 在 Disgust class 上的重大缺點。

4. (1.5%, each 0.5%)CNN time/space complexity:

   a.
       Layer A: (2\times2\times5+1)\times6=126 (parameters)
      Layer B: (2\times2\times6+1)\times4=100 (parameters)

weight bias
   b. Layer A:
              each kernel-size calculations takes Z wix;
                     making 19 additions, 20 multiplications;
              there are 6 filters, each filter perform 3×3 times,
             so 19 \times 6 \times 3 \times 3 = 1026 additions and
                   20×6×3×3 = 1080 multiplications are needed.
      Layer B:
             there are 4 filters, each kernel has 2×2×6=24 weight params,
             each filter perform Ix I time I
             so (24-1)\times 4\times |x| = 92 additions and
                    24 \times 4 \times | \times | = 96 multiplications are needed
    c. each layer: O\left(\left[k^2C_{i-1}+\left(k^2C_{i-1}-1\right)\right]\times C_i\times\left[\left\lfloor\frac{n+2p-k}{5}\right\rfloor+1\right]\right)
                     = O ((k2(A+2p-k)+s) C;-12 C;)
       denote k^2(n+2p-k)=5 as K_i for loyer i
     \Rightarrow total time complexity = O\left(\sum_{i=1}^{l} K_i(C_{i-1})^2 C_i\right)
